ABSTRACT:

The multiple acoustic protective glazing (1)

mounted in a window is claimed comprising a first laminated glass panel (2) and at least a second plain glass panel (3), parallel to the first panel and separated from it by a gas lamina (4). The panels are assembled in an airtight manner and the sheets (5, 6) of glass in the laminated panel are joined together by at least one plastics film (7) giving some properties highly sound-proofing and-or of low inflexibility. The laminated glass panel incorporates at least two glass sheets (5, 6) with a thickness of 1-3.2 mm and the plain glass panel has a thickness of 2.8-8.2 mm such that it is equal or greater than the thickness of the laminated glass panel. The gas lamina has a thickness of 6-20 mm and preferably has a thickness of 12 mm. The plastics film joining the two glass panels is made up of a resin such that a stretcher of 9cm in length and 3 cm in width, constituting a laminated glass incorporating two sheets of glass of 4 mm in thickness joined together by a 2 mm layer of the resin, having a resonance frequency of primary mode (f_c) that differs by more than 35% from that of a stretcher of monolithic glass having the same length, the same width and a thickness of 4 mm. The thickness of the plastics film is equal to or greater than 0.38 mm.
